Abstract

Detecting of weapons hidden underneath a person’s cloths is very much important for the improvement of security of the public as well as the safety of public assets like airports, buildings, and railway stations etc. Manual screening procedure gives unsatisfactory results when the object is not in the range of security personnel and when there is an uncontrolled flow of people. Our goal is to develop an automatic detection and recognition system of concealed weapons using sensor technologies and image processing. The main aim of this paper is to develop a new algorithm which uses a color visual image and a corresponding IR image for such a concealed weapon detection application by the help of fusion technology.

Keywords: CWD(Concealed weapon detection), Color & Inverted image, IR image, DWT image fusion

1.Introduction

A weapon is any object that can do harm to another individual or group of individuals. This definition not only includes objects typically thought of as weapons, such as knives and firearms, but also explosives, chemicals, etc. so this harmful things need to be detect for securing general public as well as public assets like airports and buildings etc. Already used manual screening procedure sometimes gives wrong alarm indication, and fails when the object is not in the range of security personnel as well as when it is impossible to manage the flow of people through a controlled procedure. It also disappoints us when we try to identify a person who is the victim of an accident in future. In recent times we have witnessed a series of bomb blasts. Bombs went off in buses and underground stations, killed many and left many injured and left the world in shell shock and the Indians in terror. This situation is not limited to India but it can happen or already happened anywhere and anytime in the world. People think bomb blasts can’t be predicted before handled. In all of these cases CWD by scanning the images gives satisfactory results. But no single sensor technology can provide acceptable performance. So we try to bring the eventual deployment of automatic detection and recognition of concealed weapons. It is a technological challenge that requires innovative solutions in sensor technologies and image processing. Now image fusion has been identified as a key technology to achieve improved CWD procedures. In our current work we focus on fusing visual and low cost IR images for CWD.

Infrared images are depends on the temperature distribution information of the target to form an image. Usually the theory follows here is that the infrared radiation emitted by the human body is absorbed by clothing and then re-emitted by it. In the IR image the background is almost black with little detail because of the high thermal emissivity of body. The weapon is darker than the surrounding body due to a temperature difference between it and the body (it is colder than human body). The visual image is a mental image that is similar to a visual perception. The resolution in the visual image is much higher than that of the IR image. It is nothing but a RGB image that supports human visual perception. But there is no useful information on the concealed weapon in the visual image. The human visual system is very sensitive to colors. To utilize this ability if we apply this image with other image in fusion technique we get a better fused image that helps for detection.

2. Literature Survey

Imaging techniques based on a combination of sensor technologies and processing will potentially play a key role in addressing the concealed weapon detection problem. One critical issue is the challenge of performing detection at a distance with high probability of detection and low probability of
false alarm. Yet another difficulty to be surmounted is forging portable multisensory instruments. Also, detection systems go hand in hand with subsequent response by the operator, and system development should take into account the overall context of deployment [1]. Concealed Weapon using the radar image are proposed by Yu-Wen Chang et al. [2,3] in which drawbacks such as glint and specular reflection or artifacts such as coherent interference these problems should be able to be overcome. A new algorithms proposed by Zhiyun Xue et al.[6] in which fuse a color visual image and a corresponding IR image for such a concealed weapon detection application in which they have great success. So fusion is an important step, we use here DWT fusion, some more improve method are there such as Chu-Hui Lee et al.[13] produce a easy applications to adjust for anytime, and anywhere you like, make sure that may work and take a photograph nicely. The DWT fusion methods provide computationally ancient image fusion techniques Various fusion rules for the selection and combination of sub band coefficients increase the quality perceptual and quantitatively measurable of image fusion in specific applications. For binaries the fused image there are several method[8-10] Otsu method are chosen because this method is global method and effective for this type of image. The concept of small area removal are taken from[4]. However, based on biological research results, the human visual system is very sensitive to colours. To utilize this ability, some researchers map three individual monochrome multispectral images to the respective channels of an RGB image to produce a false color fused image. In many cases, this technique is applied in combination with another image fusion procedure. Such a technique is sometimes called color composite fusion. we present a new technique to fuse a color visual image with a corresponding IR image for a CWD application.

3. Proposed Method:
In our proposed technique for CWD we consider two types of image – a visual image and an IR image. Visual image is nothing but an RGB image which has three main colour components Red, Green and Blue. Since the human visual system is very sensitive to colours this image creates a natural perception of an object to human vision but not helps so much in the detection of concealed weapon. For this we consider IR image as second input. It basically depends on high thermal emissivity of the body. Basically the infrared radiation emitted by the body is absorbed by clothing and then re-emitted by it, is sensed by the infrared sensors. Due to difference in thermal emissivity we can realize the hidden object but since the background is almost black this image cannot help in CWD alone.

**Resize two input images:** Since these two input images are taken from two different image sensing devices so they are of different size. So we first resize these two types of images because the image fusion and other operations are not possible if the sizes are not same.

**Combine two images:** Perform the addition operation between visual and IR (visual + IR) images to get the $I_{v\_IR}$ image. But the resultant image does not give enough information. Then we complement the IR image ($IR_{c}$) to remove the background darkness. IR image lies the intensity between 0 to 255 intensity thus complement means subtracting all matrix component from 255 and we get complemented form or reverse form of the IR image. Then add visual image and complemented IR image (visual + complemented IR) and get a resultant image which is denoted by $I_{v\_IR_{c}}$

**Conversion of IR to HSV:** Then we convert IR image into HSV colour model ($IR_{HSV}$) because components of IR image are all correlated with the amount of light hitting the object, and therefore with each other, image descriptions in terms of those components make object discrimination difficult. Descriptions in terms of hue/lightness/saturation are often more relevant.

**Fused two images:** After converting HSV model the image is now three components. Now we can use fusion technique because two images have the same dimension with same size and we use DWT fusion technique between HSV colour image ($IR_{HSV}$) and combined image $I_{v\_IR_{c}}$. Processing for showing the weapon clearly in the visual image: Then this fused image converted into gray scale image. Now we use Otsu’s local thresholding technique for binarizing fused gray scale image. Then Extract the weapon portion by calculating all connected area component and remove too small component and also too large component according to the area values. To show the weapon in the actual RGB visual image we multiply the weapon’s binary images with three dimensional RGB image. Basically the element wise multiplication is performed between two matrices. Now contour detection is used to detect edges of weapon from the weapon binary image and we use canny edge detector for detecting the
edges. Then this binarizes contour image is divided into three components and multiply as before and we get contour with visual RGB image where we can detect the concealed weapon under the person’s clothes very clearly. Here below is an algorithm for our proposed work:

**Algorithm:**

1. Take a visual image (basically, RGB image) and an infrared (IR) image as input.
2. Resize this two image so that they have same size.
3. Combine i.e. add resized Visual and IR image.
4. Complement the IR image
5. Combine i.e. add resized Visual image and complemented IR image.
6. Convert the visual RGB image to its HSV format.
7. Perform DWT fusion on Step 5’s combined image and Step 6’s converted HSV image.
8. Convert the fused image into its gray scale format.
9. Binarize the Fused image
10. Detect the weapon from that image.
11. Combine the detected weapon with visual image.
12. For detecting the weapon clearly we find out the contour of the weapon.
13. Then combine the contour of the weapon with visual image.
14. End

**4. Result And Analysis:**

The weapons detection algorithm consists of several steps which will be explained in detail in the following. Take two images in the same pose visual RGB image and IR image which are shown in **figure 1** and **figure 2**. Resize these two types of image because image fusion and addition are not able to perform if the sizes are not same.

Combine basically add visual image and IR image and the result is shown in **figure 3**. Actually we want to detect the hiding details from **figure 3** but image from **figure 3** is hazy, so we do not get enough information from **figure 3**. Complement the IR image which is useful in the next operation and this complement image is shown in **figure 4**. IR image lies the intensity between 0 to 255 intensity thus complement means subtracting all matrix component from 255 and we get complemented form or reverse form of the IR image. Then add visual image and complemented IR image which is shown in **figure 5**.
In this step fusion is not possible due to dimension mismatch. We do these steps because in this step difference between hiding details and man are recognizable. Then we convert IR image into HSV colour model and it is shown in figure 6 because components of IR image are all correlated with the amount of light hitting the object, and therefore with each other, image descriptions in terms of those components make object discrimination difficult. Descriptions in terms of hue/lightness/saturation are often more relevant. After converting HSV model the image is now three components. Now we can use fusion technique because two images have the same dimension with same size. Then we use DWT fusion technique between HSV color image and combined image is shown in figure 7. In wavelet transformation due to sampling, the image size is halved in both spatial directions at each level of decomposition process thus leading to a multi-resolution signal representation. The advantages of image fusion over visual comparison of multi-modality are: (a) the fusion technique is useful to correct for variability in orientation, position and dimension; (b) it allows precise anatomic, physiologic correlation; and (c) it permits regional quantisation. Many image processing like de-noising, contrast enhancement, edge detection, segmentation, texture analysis and compression can be easily and successfully performed in the wavelet domain. Applying fusion technique image sharpness and contrast enhanced. Then this fused image converted into gray scale image is shown in figure 8.

This step is required for the next step in which we use a binarization technique. There are several binarization techniques among them Otsu, Bernsen, savala, th-mean, niblack and iterative partitioning as a framework method are showing good result for this type of image. Here we use Otsu method which is a global Thresholding method i.e threshold value are calculated locally and get the result, no extra threshold value is added here. Extract this weapon portion by calculating all connected area component then remove too small component according to the area values. This only weapon portion binary image is shown in figure 9. Let us we want to show the weapon in the actual RGB visual image. The weapon binary images are stored into three different components because we want multiply it with three dimensional RGB image. Multiply individual element to element between two matrices. In this step we detect weapon with visual RGB image is shown in figure 10.
Contour detection is used to detect edges of weapon from the weapon binary image. Edge detection refers to the process of identifying and locating sharp discontinuities in an image. The discontinuities are abrupt changes in pixel intensity which characterize boundaries of objects in a scene. There is an extremely large number of edge detection operators available, each designed to be sensitive to certain types of edges. Here we use canny edge detection techniques. The Canny edge detection algorithm is known to many as the optimal edge detector. Canny's edge detection algorithm is computationally more expensive compared to Sobel, Prewitt and Robert's operator. However, the Canny's edge detection algorithm performs better than all these operators under almost all scenarios. This contour detection of concealed weapon is shown in **Figure 11**.

Then this binarizes contour image are divided into three component and multiply as before and get contour with visual RGB image which is shown in **Figure 12** where we can see the concealed weapon under person clothes easily.
5. Conclusion
Here we have introduced a color image fusion technique for CWD where we fuse a visual RGB image and IR image. We can able to detect the weapon concealed under person’s clothes and bags. But infrared radiation can be used to show the image of a concealed weapon only when the clothing is tight, thin, and stationary. For normally loose clothing, the emitted infrared radiation will be spread over a larger clothing area, thus decreasing the ability to image a weapon. We try to solve this problem in our future work.
